Methodology for Evaluating Pesticides for Surface Water Protection I: Initial Screening

Yuzhou Luo, Ph.D., and Xin Deng, Ph.D.

October 12, 2011

Terminology of Chemical Properties

AERO	aerobic soil metabolism half-life, day
AERO_W	aerobic aquatic metabolism half-life, day
ANAER	anaerobic soil metabolism half-life, day
ANAER_W	anaerobic aquatic metabolism half-life, day
FD	field dissipation half-life, day
HLW	dissipation half-life in water, day
HLD	dissipation half-life in sediment (or water-sediment system), day
HYDROL	hydrolysis half-life, day
KOC	organic carbon-normalized soil adsorption coefficient, L/kg[OC]
LC ₅₀	median lethal concentration, ppb
SOL	water solubility, mg/L

1. Introduction

The Surface Water Protection Program (SWPP) is developing a more consistent and transparent method for evaluating registration packages. Historically, these evaluations have been based principally on professional judgment and experience gleaned from past assessment of the conditions and mechanisms responsible for the offsite transport of pesticides to surface water and their associated toxicological impact on aquatic life. A two-phase procedure is proposed here, including phase (I) evaluation with initial screening, and phase (II) evaluations with refined modeling (Figure 1). Initial screening is conducted solely on chemical properties (soil adsorption coefficient, water solubility, and reaction half-lives) and aquatic toxicology data of the active ingredient in evaluation. The objective of the phase I evaluation is to classify pesticides as to whether they [1] are unlikely to be a surface water quality problem, and their registrations are supported without conditions, or [2] may potentially cause surface water problems and require additional evaluation. *This document (Part I) outlined the initial screening procedure to evaluate pesticides for the protection of surface water quality.*

For pesticides requiring additional evaluations, phase II evaluation is followed with a more refined modeling approach *as presented in a companion report (Part II)*. Phase II evaluation is

performed based on risk characterization by accounting for the product-specific information (use pattern and application rate). The objective of phase II evaluation is to develop registration recommendations for pesticide products as whether [1] to support registration without conditions, [2] to support conditional registration with requests for analytical methods, or [3] not to support registration.

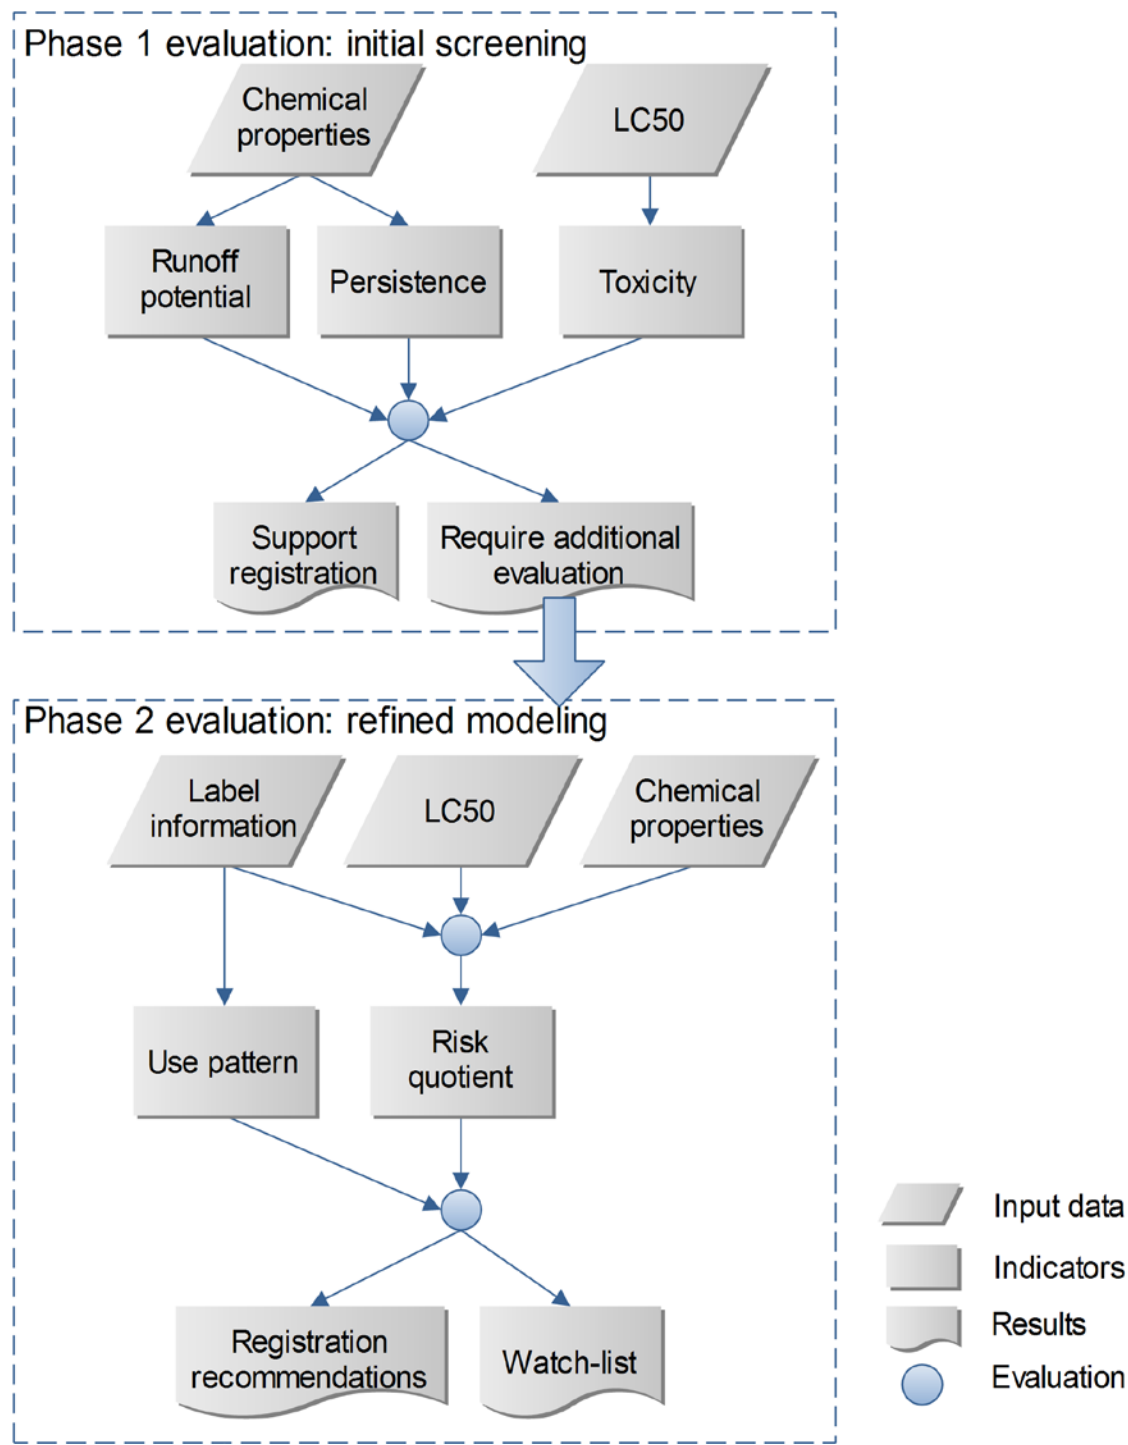

Figure 1. Schematics of the two-phase procedure of pesticide evaluation for surface water protection

The methodology addresses both water column and sediment-bound phases and considers different use patterns of a pesticide. Except for the use pattern, all other indicators (Figure 1) are defined for pesticides in both water column (aqueous phase) and sediment (adsorbed phase). Evaluation for aqueous phase is conducted for all pesticides, while evaluation for adsorbed phase is only required for pesticides with KOC > 1000. This criterion is set based on the USEPA data requirement for pesticide registration, in which acute sediment toxicity is required for pesticides with KOC > 1000 (USEPA, 2007a). In addition, a pesticide product may be associated with multiple use patterns. Pesticide evaluation could be conducted for each of the use patterns. The final registration recommendation will be based on both the evaluation results and professional judgment with additional information from the chemical properties and product label.

2. Methods and Materials

2.1. Indicators for Phase I Evaluation

Three indicators are developed for pesticide active ingredient: [1] runoff potential, [2] aquatic persistence, and [3] aquatic toxicity. These indicators were derived from the registrant-submitted data, and assigned as descriptive classifications, i.e., “low”, “intermediate”, “high”, and/or “very high” (for toxicity only) classes. Based on the data availability in a regular registration package and the objectives in this project, we selected dissipation half-lives, water solubility, KOC, and aquatic toxicity value as input parameters for developing the indicators. According to the evaluation matrix presented in Table 1, the resulting indicators provide an initial screening of the environmental distribution and aquatic risks of the pesticide active ingredient. *Detailed information for the development of the three indicators is provided in the following sections.*

Table 1. Evaluation matrix for initial screening

Indicators			Results	Recommendations
Runoff potential	Persistence	Toxicity		
H	L	H	The chemical may potentially cause surface water problem	Require addition evaluation
H	M or H	H	The chemical may pose too high of a potential surface water risk	
Everything else			The chemical is unlikely to cause surface water problems	Support registration

Notes: indicator ratings: “L” = low, “M” = intermediate, “H” = high or very high

2.2. Runoff Potential

A screening approach developed by U.S. Department of Agriculture (USDA) (Goss, 1992) was modified for rating pesticide runoff potential. The approach was developed from over 40,000 runs of the Groundwater Loading Effects of Agricultural Management System (GLEAMS) using a wide range of soil and pesticide properties to estimate pesticide loss from soils through runoff processes. Based on a stepwise regression, physiochemical properties of field dissipation half-life (FD), KOC, and water solubility were identified as input parameters that weighted most

heavily for estimating each group of pesticide loss potentials from the model runs. The groups for pesticide loss potentials are classified as: “high”, “intermediate”, and “low”. Multiple regression equations were used for each group in order to capture the highly nonlinear relationship between runoff potential and the input parameters. The USDA rating approach is currently used in the WIN-PST (Windows Pesticide Screening Tool) program (USDA, 2010).

Preliminary tests indicated that the USDA rating approach underestimated the runoff potential for pesticides with high KOC or high water solubility. For example, several pyrethroids were classified with only “intermediate” runoff potentials mainly because their field dissipation half-lives were less than 40 days. However, pyrethroids are known to bind strongly to and persist in soils and sediments, and to be toxic to many aquatic invertebrates at very low concentrations. Pyrethroids-associated sediment toxicity have been recognized in California (CEPA, 2010), and they are currently in reevaluation to address these concerns (CDPR, 2006). The other identified issue is that, the USDA rating approach excludes all pesticides with a solubility greater than 100 mg/L, such as organophosphates (dimethoate, malathion, and methidathion), from being classified as having “high” runoff potential. This is not consistent with the fact that organophosphates are frequently detected in surface waters (Pepple, 2009). Therefore, we revised the USDA rating approach for the group of “high” runoff potentials to cover the pesticides with frequent detection in surface water or high toxicity in sediment (Table 2). Testing for the revised model is provided in Section 3.1. If field dissipation half-life is not available in the registrant-submitted data, aerobic soil metabolism half-life will be used for runoff potential rating.

Table 2. Algorithm expressing pesticide runoff potential from soils

(a) Pesticide adsorbed-phase runoff potential

Criteria	Runoff potential rating
Revised criteria in this project ($FD \geq 15$ and $KOC \geq 4 \times 10^4$) or ($FD \geq 40$ and $KOC \geq 1000$) or ($FD \geq 40$ and $KOC \geq 500$ and $S \leq 0.5$)	High (H)
<i>Original USDA criteria</i> ($FD \geq 40$ and $KOC \geq 1000$) or ($FD \geq 40$ and $KOC \geq 500$ and $S \leq 0.5$)	
($FD \leq 1$) or ($FD \leq 2$ and $KOC \leq 500$) or ($FD \leq 4$ and $KOC \leq 900$ and $SOL \geq 0.5$) or ($FD \leq 40$ and $KOC \leq 500$ and $SOL \geq 0.5$) or ($FD \leq 40$ and $KOC \leq 900$ and $SOL \geq 2$)	Low (L)
Everything else	Intermediate (M)

(b) Pesticide solution-phase runoff potential

Criteria	Runoff potential rating
Revised criteria in this project ($SOL \geq 1$ and $FD > 20$ and $KOC < 1 \times 10^5$) or ($SOL \geq 10$ and $KOC \leq 2000$)	High (H)
<i>Original USDA criteria</i> ($SOL \geq 1$ and $FD > 35$ and $KOC < 1 \times 10^5$) or ($SOL \geq 10$ and $KOC \leq 700$ and $SOL < 100$)	
($KOC \geq 1 \times 10^5$) or ($KOC \geq 1000$ and $FD \leq 1$) or ($SOL < 0.5$ and $FD < 35$)	Low (L)
Everything else	Intermediate (M)

Note: modifications are made only for the criteria of “high” runoff potential, while no changes for other classes.

Pesticides vary in their runoff potential depending on their different use pattern. Some pesticides are directly applied or released into water bodies without experiencing soil runoff processes, such as herbicides for rice production, pesticides for the control of mosquito and midge larvae in surface water, or those used in antifouling paint products. In this case, the runoff potential rating was skipped and “high” runoff potential was assumed for both absorbed and dissolved phases as a conservative assumption.

2.3. Aquatic Persistence

Pesticides were grouped into three categories based on their half-lives in aquatic systems: “low” persistence with a typical aquatic half-life of less than 30 days, “intermediate” persistence with a half-life of 30 to 100 days, and “high” persistence with a half-life of more than 100 day (Table 3). The breakout points were suggested by Kerle et al. (2007). For pesticide persistence in water phase, aquatic dissipation half-life (HLW) value is determined as the shortest values of hydrolysis half-life, aerobic aquatic metabolism half-life, and dissipation half-life in water phase. For persistence in sediment, USEPA suggested that dissipation half-life in sediment could be taken from the anaerobic soil or aquatic metabolism studies (USEPA, 2007a).

Table 3. Pesticide persistence in water and sediment (half lives in days)

Criteria	Persistence rating
$HLW \geq 100$	High (H)
$30 \leq HLW < 100$	Intermediate (M)
$HLW < 30$	Low (L)

2.4. Aquatic Toxicity

Toxicity ratings are determined by the acute toxicity value (LC_{50} , median lethal concentration) of the most sensitive species (Table 4). Acute toxicity data requirements for freshwater and saltwater organisms including fish and invertebrates in water and sediment follow the definitions and conditions described in USEPA 40 CFR §158.630 and §158.660 (USEPA, 2007a) for

protection of non-target aquatic organisms. Acute toxicity tests should be conducted using acceptable procedures recommended by USEPA. Acceptability of acute toxicity data should be evaluated based on the USEPA guidelines for deriving numerical national water quality criteria for aquatic organisms and their uses (USEPA, 1985). For sediment toxicity, only a few pesticides were tested and the corresponding toxicity ratings are not readily available. Existing data show that pyrethroids are a group of pesticides considered to be most toxic to the benthic invertebrate *Hyalella azteca* and their LC₅₀ values are generally below 10 µg/g[OC]. In this project, pesticides with sediment LC₅₀ values below/equal to 10 µg/g[OC] are classified as the highest toxic category. This critical value was scaled up in a 10 fold fashion to determine other toxicity ratings of high, intermediate, slight, and practically nontoxic categories in the sediment, respectively. The 10-fold scale is consistent with that used in rating water column toxicity (Table 4). Toxicity values for aquatic plants are not considered because these toxicity data are not required for pesticide registration by USEPA (2007a) and current plant toxicity tests usually measure endpoints such as growth and reproduction that are generally associated with chronic toxicity. Moreover, the algal toxicity test guide in Environmental Toxicology Standards (ASTM, 2004) states that an algal toxicity test of short duration (72, 96 or 120 h) should not be viewed as an acute toxicity test because it examines effects upon multiple generations of an algal population.

Table 4. Descriptive acute toxicity ratings for pesticides in water column and sediment

Toxicity rating	Water column (µg/L)	Sediment (µg/g[OC])
<i>Very high (VH)</i>	LC ₅₀ ≤ 100	LC ₅₀ ≤ 10
<i>High (H)</i>	100 < LC ₅₀ ≤ 1000	10 < LC ₅₀ ≤ 100
Intermediate (M)	1000 < LC ₅₀ ≤ 10000	100 < LC ₅₀ ≤ 1000
Slight (L)	10000 < LC ₅₀ ≤ 100000	1000 < LC ₅₀ ≤ 10000
Practically nontoxic (L)	LC ₅₀ > 100000	LC ₅₀ > 10000

Note: water column toxicity is rated by following the descriptive classifications by USEPA (Zucker, 1985).

According to USEPA (2007a), for all pesticides with KOC > 1000, acute sediment toxicity test is required for pesticide registration. In the demonstration of the developed approach (Section 3.2), however, sediment toxicity data is not available for some of the previously evaluated pesticides. In this case, we assumed that the sediment toxicity of a pesticide could be estimated as the product of its water toxicity and KOC value. Please note that this assumption was only utilized in the methodology testing, while in the real evaluation processes the actual sediment toxicity for the evaluated active ingredient should be used. Details of the data analysis for comparing pesticide acute toxicity in water and sediment are provided in the Appendix #1.

3. Methodology Testing

3.1. Test for Runoff-Potential Rating

As part of the methodology testing, the indicator of runoff potential was first rated for 172 pesticides with the E-fate database compiled by Spurlock (2008). Detailed test results are presented in the Appendix #2. Pesticides with high runoff potential identified in the test results

were generally consistent with those frequently detected in surface water (Pepple, 2009) or currently in reevaluation for sediment toxicity (CDPR, 2006).

3.2. Test for the Initial Screening Procedure

3.2.1. Selection of Pesticides

Two sets of pesticides were selected to test the evaluation approach. The first set of pesticides was selected from the registration evaluations by the Environmental Monitoring Branch. The following filters were used in the selection:

1. evaluations for surface water protection,
2. evaluations supplied with both chemical property data and toxicity data, and
3. evaluations posted during 2008-2010 (as of July 2010 when the study was initialized).

With all of the above filters applied, 21 pesticide active ingredients were selected and denoted with “A” to “U” in the demonstration. The registration packets and evaluation reports were used as the data source for chemical properties and toxicity data.

The second set of pesticides was suggested by scientists from the Environmental Monitoring Branch and the Registration Branch. These pesticides included bifenthrin, chlorpyrifos, diazinon, diuron, fipronil, and simazine, which are known surface water contaminants and/or are currently under re-evaluation. Chemical properties for the six pesticides were obtained from FOOTPRINT database (FOOTPRINT, 2010). Toxicity data was retrieved from multiple sources (NPIC, 2010; UCD, 2010a, 2010b, 2010c, 2010d; USEPA, 2010c). Input data for the two sets of pesticides are listed in Table 5 (chemical property data) and Table 6 (toxicity data).

3.2.2. Data Acquisition

The physicochemical properties and degradation half-lives for selected pesticides were retrieved from the registration evaluation reports or from the literature (Table 5). If multiple numerical values are available for a parameter, their geometric mean will be used in the calculation of indicators. If only a range is provided, the mean value of the upper and lower bounds will be applied.

Table 5. Summary of physicochemical property and degradation half-lives for selected pesticides

Active ingredient	SOL	KOC	HYDROL	AERO	ANERO	FD	AERO_W	ANERO_W	HLW	HLD
A	0.28	35838	30	15.8	200					
B	2.8	459	365			69			45	126.7
C	2.56	1580		101	60	77			29	163
D	2100	27	270			34			30	60
E	130	252	999	1358		1358		999		999
F	0.0225	17757	999	15			32	174		
G	0.17	11708	3				31	71		
H	22	1294	999	618	120			999	8	485
I	0.33	24300	34			90		105	4	16
J	180.6	7044	999	999		1400				
K	2040	23.5	16			23				26
L	200	576	9.9			2.2		0.56		
M	30	225				1.13	2.48	2.48		
N	2.8	328	365	365		271			91.4	777
O	78100	68.5				7				
P	15	3760		120		85			3	1053
Q	1	339.5	30			222	231	208	0.37	
R	150	1086	53.5			214			6	636
S	0.44	5247	97			0.2			0.15	0.13
T	0.492	2559	999			146			3.9	9.3
U	429	193.8	999	78	48	56			129	250
chlorpyrifos	1.05	8151	25.5			21			5	36.5
diazinon	60	643	138			18.4			4.3	10.4
diuron	35.6	1067	999			89			8.8	48
bifenthrin	0.001	236610	999			84.6			8	251
simazine	5	130	96			90			46	33
fipronil	3.78	577	999			65			54	68

Notes:

- 1) For the first 21 pesticides, data was retrieved from registration packets and evaluation reports. For the last 6 pesticides, data was taken from FOOTPRINT database (FOOTPRINT, 2010)
- 2) A value of 999 is set as a numerical value for the “stable” reaction processes. This is used for the convenience of programmatic data processing.

For toxicity data, acute toxicity values for freshwater and saltwater fish and invertebrate species were considered (Table 6). The most sensitive species (i.e., with lowest LC₅₀ or EC₅₀) was used for toxicity rating. Toxicity values for aquatic plants were not considered in the current evaluation process because data are not required for registration by USEPA and measured toxicity endpoints (i.e., growth and reproduction) for aquatic plants are usually associated with chronic toxicity.

Table 6. Aquatic acute toxicity values (µg/L) for selected pesticides

Active ingredient	Rainbow trout	Bluegill/fathead minnow	<i>Daphnia magna</i>	Mysid shrimp	Sheepshead minnow
A	30000	5940	92670	N/A	7870

simazine	>10000	6400	1000	N/A	>4300
fipronil	246	83	190	0.14	N/A

Notes: For the first 21 pesticides, data was retrieved from registration packets and evaluation reports. For the last 6 pesticides, data was taken from multiple sources (NPIC, 2010; UCD, 2010a, 2010b, 2010c, 2010d; USEPA, 2000, 2007b, 2007c, 2010b, 2010c).

3.2.3. Derived Indicators

The rating criteria (Tables 2-4) are applied to the input data in Tables 5 and 6. Resulting indicators of runoff potential, persistence, and freshwater toxicity are shown in Table 7.

Table 7. Classification of runoff potential, persistence, and freshwater toxicity for the selected pesticides ^{(1),(2)}

Active ingredient	Aqueous runoff potential	Persistence in water	Freshwater toxicity	Sediment runoff potential	Persistence in sediment
A ⁽³⁾	H	M	M	H	H
B	H	M	H	M	H
C	H	L	VH	H	H
D	H	M	M	L	M
E	H	H	L	M	H
F	L	M	VH	M	H
G ⁽³⁾	H	L	VH	H	L
H	H	L	H	H	H
I ⁽³⁾	H	L	H	H	L
J	H	H	M	H	H
K	H	L	L	L	L
L	H	L	L	L	L
M	H	L	M	L	L
N	H	M	H	M	H
O	H	L	M	L	L
P	H	L	H	H	H
Q	H	L	VH	M	H
R ⁽³⁾	H	L	H	H	H
S ⁽³⁾	H	L	H	H	L
T	M	L	H	H	L
U	H	H	L	M	H
chlorpyrifos	H	L	VH	M	M
diazinon	H	L	VH	L	L
diuron	H	L	M	H	M
bifenthrin	L	L	VH	H	H
simazine	H	M	H	M	M
fipronil	H	M	VH	M	M

Notes:

- 1) “L”=Low, “M”=Intermediate, “H”=High, and “VH”=Very High (for toxicity only, Table 4)
- 2) Sediment toxicity values are not available for most of the selected pesticides (except for bifenthrin, chlorpyrifos, and fipronil, as provided in appendix #1), and estimated from the corresponding water toxicity and KOC value. Please refer to Section 2.4 and Appendix #1 for details. The estimated sediment toxicity is only used to demonstrate the proposed procedure of initial screening.
- 3) For pesticides released directly into water, the runoff potential is assumed to be “high” for both absorbed and dissolved phases. See Section “2.2 Runoff Potential” for more details on this assumption, and the report part 2 for the pesticide use patterns associated with the evaluated products.

3.2.4. Initial Screening Results

Demonstrated in Table 8 are the results of initial screening for the selected pesticides, in comparison with the registration recommendations based on best professional judgment, retrieved from the evaluation reports. Sediment toxicity was not available for most of the selected pesticides, and the toxicity rating was based on the corresponding water toxicity. Therefore, the validation of the proposed method was focused on the dissolved phase. Generally, the procedure of phase I evaluation generates consistent or conservative results compared to the recommendations by best professional judgment (Table 9). Therefore, we concluded that, the proposed initial screening has the capability to identify pesticides which [1] are unlikely to cause surface water problems, or [2] may cause potential problems and require additional evaluation.

Table 8. Recommendations from model-based evaluation vs. best professional judgment for surface water protection ⁽¹⁾

Active ingredient	Recommendations by phase I evaluation		Best professional judgment based recommendations
	Dissolved phase	Adsorbed phase (2)	
A	S	S	S
B	R	-	S
C	R	R	C (sed. toxicity test & runoff test)
D	S	-	S
E	S	-	S
F	S	S	S
G	R	R	C (marina test)
H	R	S	C (sed. toxicity test)
I	R	S	S
J	S	S	C (sed. toxicity test)
K	S	-	S
L	S	-	S
M	S	-	S
N	R	-	C (runoff test)
O	S	-	S
P	R	S	S
Q	R	-	C (runoff test)
R	R	S	N
S	R	S	S
T	S	S	S
U	S	-	S
chlorpyrifos	R	S	
diazinon	R	-	
diuron	S	S	
bifenthrin	S	R	
simazine	R	-	
fipronil	R	-	C (runoff test)

Notes:

- 1) “S” = support registration without conditions; “N” = not support registration; “C” = support conditional registration; and “R” = require additional evaluation. “Best professional judgment based recommendation” was the original recommendations in the evaluation reports.
- 2) Evaluations for sediment-bound pesticides were only conducted for those with KOC > 1000, for which USEPA requires sediment toxicity tests (USEPA, 2007a). For pesticides without reported sediment toxicity, we estimated sediment toxicity from the corresponding water toxicity. Therefore, the evaluation results for adsorbed pesticides won’t be used in the comparisons best professional judgment based recommendations.

Table 9. Summary of the initial screening results

Active ingredients	Recommendations by phase I evaluation (dissolved phase)	Best professional judgment based recommendations	Notes
A, D, E, F, J, K, L, M, O, T, and U	S	S	Consistent results
C, G, N, Q, and R	R	C (runoff test) or N	Consistent results
B, H, I, P, and S	R	S or C (sed. toxicity test)	Conservative results

4. Discussion and Conclusion

1. The proposed methodology serves as an initial screening tool for assessing runoff potential, persistence and toxicity of a pesticide active ingredient. Only physicochemical properties and aquatic toxicity are considered in the phase I procedure. The approach allows for an initial estimation of environmental distribution and aquatic risks of pesticides.
2. For pesticides which require additional evaluation as identified by the initial screening, we proposed a second phase to incorporate additional information such as pesticide use pattern and application rate to refine the evaluation and registration recommendations.
3. Degradates are not included in this demonstration due to limited data availability. But the same evaluation process can be applied to degradates with required chemical and toxicity data, and the final recommendation should be based on combined results for the pesticide and its degradates.
4. Toxicity for aquatic plants was not considered due to data limitations.

Appendix 1 Notes on Comparison of Pesticide Acute Toxicity on *Daphnia*, *Ceriodaphnia*, *Chironomus* and *Hyalella*

The purposes of the comparison are two folds: 1) to find out whether *Daphnia magna* and *Chironomus* or *Hyalella* LC₅₀ values are correlated and whether one can be indicative of another in toxicity rating; 2) to justify whether additional data requirement on acute toxicity of benthic invertebrates such as *Chironomus* or *Hyalella* is appropriate for the evaluation process of pesticide registration. Comparable data between species (i.e., *Daphnia* vs. *Chironomus*, *Daphnia* vs. *Hyalella*) were extracted from the OPP ecotox database (USEPA, 2010a).

Daphnia vs. *Chironomus*

Seventeen insecticides and 16 herbicides that have LC₅₀ values available for both *Daphnia magna* and *Chironomus* (*C. tentans* and *C. plumosus*) were sorted out from the OPP database (Table 1). The scattered plots (Figures 1 and 2) show poor correlations on paired LC₅₀ values between the two taxa. However, 16 out of 17 insecticides have the same toxicity ratings from both taxa (Table 1). Only 4 out of 16 herbicides are similar in toxicity rating. No correlation trend is observed in other 12 herbicides.

Daphnia vs. *Hyalella*

Only 5 pesticides with LC₅₀ values of *Daphnia* and *Hyalella* were found in the database (Table 2). There is no correlation between the LC₅₀ values of both species.

Hyalella vs. *Ceriodaphnia*

Table 3 listed *Hyalella* (water and sediment) and *Ceriodaphnia* LC₅₀ values for 5 pyrethroids, 2 OPs (chlorpyrifos and diazinon) and fipronil. In general, *Hyalella* are more sensitive to pyrethroids and fipronil but not organophosphates. However, both species are given the same toxicity rating for each chemical.

Conclusion:

- 1) There are very limited acute toxicity data available for benthic invertebrates such as *Hyalella* and *Chironomus*.
- 2) No correlations are observed in LC₅₀ values between *D. magna* and other benthic invertebrates.
- 3) For insecticides that are highly toxic to *D. magna* or *C. dubia* (LC₅₀ < 1000 ppb), it is highly likely that their toxicity ratings in benthic invertebrates will fall in the same toxicity category.
- 4) For herbicides and other pesticides with intermediate or slight toxicity to *Daphnia* or one of the invertebrates, additional toxicity data from benthic species may be helpful to re-categorize their toxicity ratings.
- 5) By combining all data pairs in the tables, most of pesticides have sediment toxicity in the same category with their corresponding category for water toxicity.

- 6) When data is not available, therefore, the category of sediment toxicity for a pesticide was set the same as the corresponding category for its water toxicity. This assumption was not made for numerically estimating the sediment toxicity, but used only for the descriptive classification of toxicity values for benthic invertebrates when the appropriate data is not available.

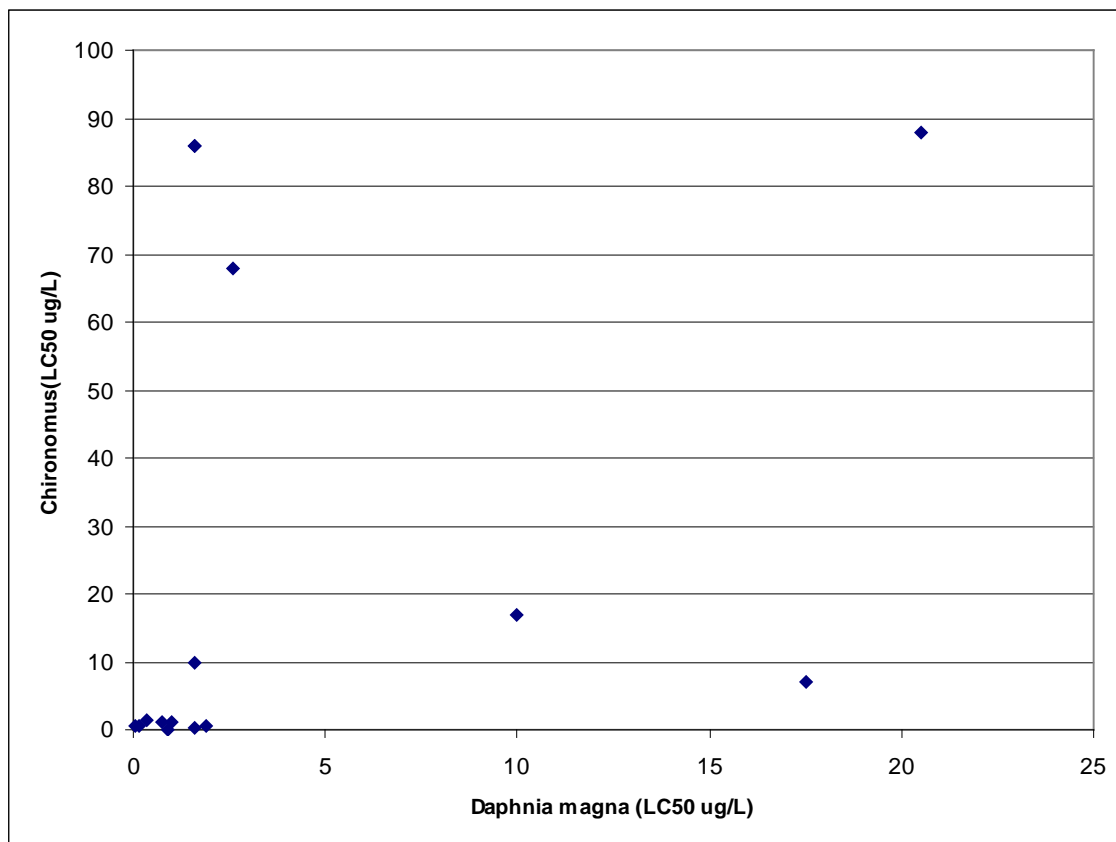

Figure 1. Scattered plot of acute toxicity between *Daphnia magna* and *Chironomus* for 15 insecticides. Note: kepone and oxamyl in Table 1 were not included because their LC₅₀ values were out of the scale of the figure scale

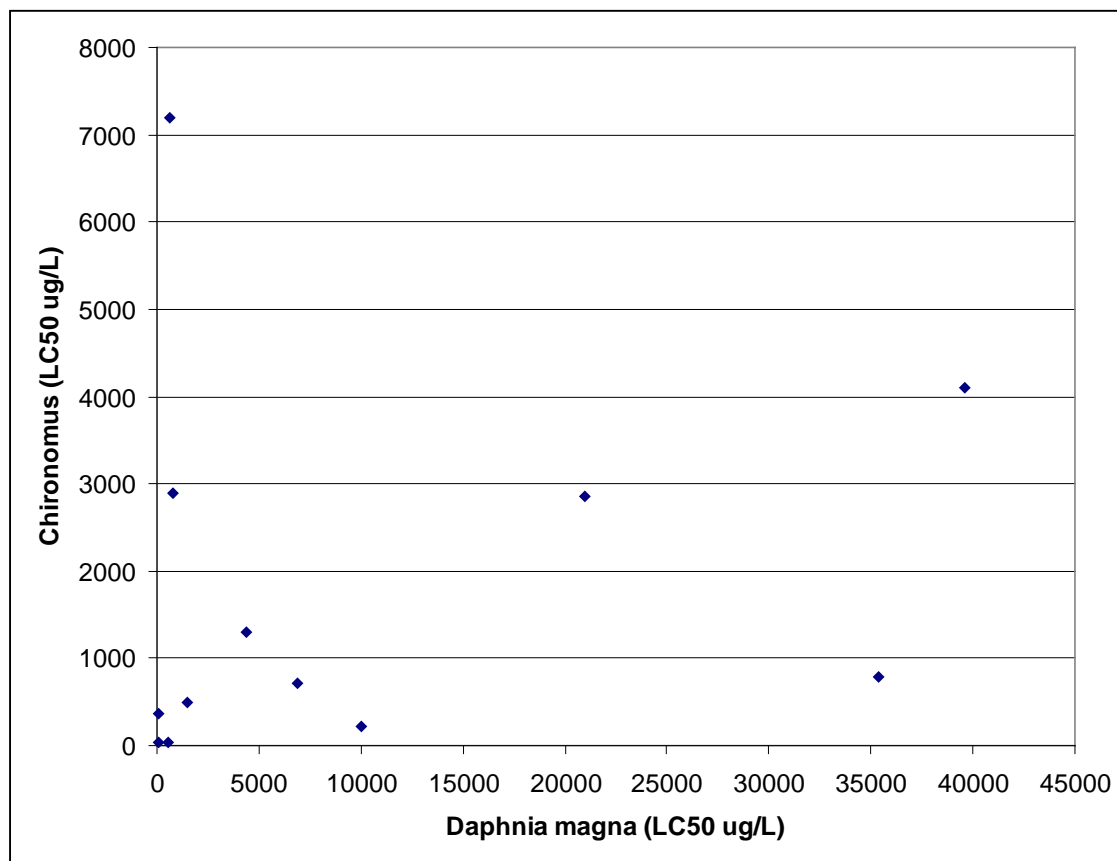

Figure 2. Scattered plot of acute toxicity between *Daphnia magna* and *Chironomus* for 12 herbicides. Note: ethephon, benomyl, chlorthal dimethyl, and glyphosate in Table 1 were not included because their LC₅₀ values were out of the scale of the figure scale

Table 1. Acute toxicity ratings of insecticides and herbicides on *Daphnia magna* and *Chironomus*

Chemical	Use pattern	Acute toxicity (LC ₅₀ µg/L)		Toxicity rating
		<i>D. magna</i>	<i>Chironomus</i>	<i>D. magna/Chironomus</i>
Bifenthrin	insecticide	1.6	0.33	VH/VH

fipronil	N/A	0.306	17.7	VH

Note: VH=very highly toxic; H=highly toxic; M=intermediately toxic; L=slightly toxic; N=non-toxic.

Appendix 2 Testing Results for Runoff-Potential Rating

Notes:

[1] Runoff potential test results for the 172 pesticides in the Efate database (Spurlock, 2008). Only “High” runoff potentials are identified as “H”, while other groups of “Intermediate” and “Low” runoff potentials are indicated by blank cells.

[2] The chemical properties in the Efate database (Spurlock, 2008) may have different values from those registrant-submitted data as shown in Table 5 and Appendix 2, and thus may result in different runoff-potential classifications.
